Exercises:

- 1. Show that the eigenvalues of $\mathbf{X}^T\mathbf{X}$ are always positive. Hint: Use that $\lambda_j = \vec{v}_i^T\mathbf{X}^T\mathbf{X}\vec{v}_j$.
- Show that for symmetric **A**, the trace is the sum of eigenvalues: $\operatorname{tr}(\mathbf{A}) = \sum_{i=1}^n \lambda_i(\mathbf{A})$. Hint: First prove the cyclic property of trace, that for any MN, $\operatorname{tr}(\mathbf{MN}) = \operatorname{tr}(\mathbf{NM})$ and then apply this to **A**'s eigendecomposition

Summary

- Many (most) datasets can be approximated via projection onto a low-dimensional subspace.
- Find this subspace via a maximization problem:

$$\max_{\substack{\text{orthonormal V}\\ \mathbf{V} \in \mathbf{D}^{\mathbf{I}_{\mathbf{X}}\mathbf{P}}}} \|\mathbf{X}\mathbf{V}\|_F^2.$$

- Greedy solution via eigendecomposition of X^TX .
- Columns of V are the top eigenvectors of X^TX .
- Error of best low-rank approximation (compressibility of data) is determined by the tail of $\mathbf{X}^T\mathbf{X}$'s eigenvalue spectrum.

The left and right singular vectors are the eigenvectors of the covariance matrix $\mathbf{X}^T\mathbf{X}$ and the gram matrix $\mathbf{X}\mathbf{X}^T$ respectively.

So, letting $V_k \in \mathbb{R}^{d \times k}$ have columns equal to $\vec{v}_1, \dots, \vec{v}_k$, we know that $XV_kV_k^T$ is the best rank-k approximation to X (given by PCA).

Writing $X \in \mathbb{R}^{n \times d}$ in its singular value decomposition $X = U \Sigma V^T$:

Similarly:
$$XX^T = U\Sigma V^T V\Sigma U^T = \underline{V\Sigma^2 V^T}$$
 (the eigendecomposition) $X = V\Sigma V^T V\Sigma U^T = \underline{V\Sigma^2 V^T}$ (the eigendecomposition)

The left and right singular vectors are the eigenvectors of the $\chi^T \bigcup_k \bigcup_k^7 \bigcup_k^7$ covariance matrix X^TX and the gram matrix XX^T respectively. $(1)_{X_1} X^T X^T$ So, letting $\mathbf{V}_k \in \mathbb{R}^{d \times k}$ have columns equal to $\vec{v}_1, \dots, \vec{v}_k$, we know that

 $XV_kV_k^T$ is the best rank-k approximation to X (given by PCA).

What about $U_k U_k^T X$ where $U_k \in \mathbb{R}^{n \times k}$ has columns equal to $\vec{u}_1, \dots, \vec{u}_k$?

 $X \in \mathbb{R}^{n \times d}$: data matrix, $U \in \mathbb{R}^{n \times rank(X)}$: matrix with orthonormal columns $\vec{u}_1, \vec{u}_2, \dots$ (left singular vectors), $\mathbf{V} \in \mathbb{R}^{d \times \mathsf{rank}(\mathbf{X})}$: matrix with orthonormal columns $\vec{v}_1, \vec{v}_2, \dots$ (right singular vectors), $\Sigma \in \mathbb{R}^{\text{rank}(X) \times \text{rank}(X)}$: positive diagonal matrix containing singular values of X.

Writing $X \in \mathbb{R}^{n \times d}$ in its singular value decomposition $X = U \Sigma V^T$:

$$\mathbf{X}^T\mathbf{X} = \mathbf{V}\mathbf{\Sigma}\mathbf{U}^T\mathbf{U}\mathbf{\Sigma}\mathbf{V}^T = \mathbf{V}\mathbf{\Sigma}^2\mathbf{V}^T \text{ (the eigendecomposition)}$$

Similarly: $XX^T = U\Sigma V^T V\Sigma U^T = U\Sigma^2 U^T$.

The left and right singular vectors are the eigenvectors of the covariance matrix X^TX and the gram matrix XX^T respectively.

What about $\mathbf{U}_k \mathbf{U}_k^T \mathbf{X}$ where $\mathbf{U}_k \in \mathbb{R}^{n \times k}$ has columns equal to $\vec{u}_1, \dots, \vec{u}_k$? Gives exactly the same approximation!
