#### N-Gram Language Models

CS 485, Fall 2024 Applications of Natural Language Processing

Brendan O'Connor

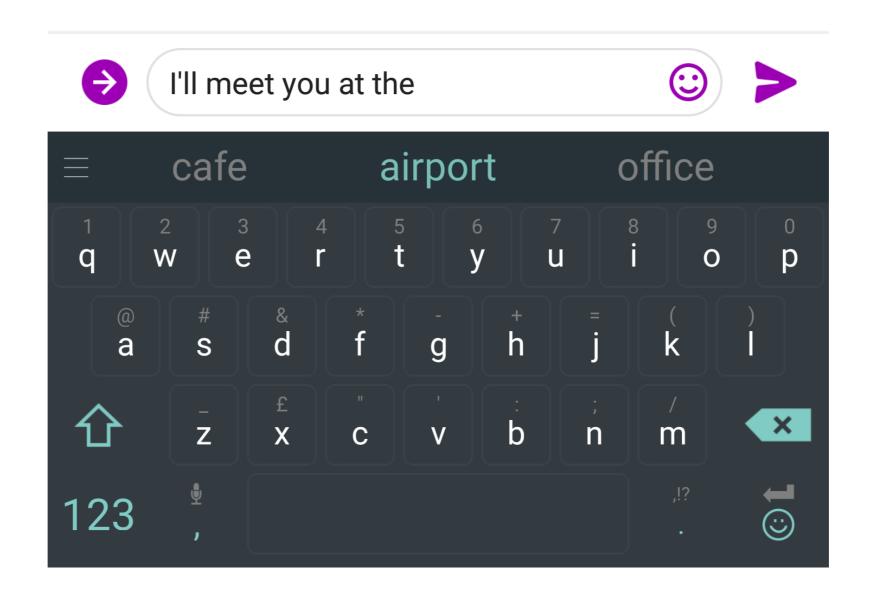

College of Information and Computer Sciences University of Massachusetts Amherst

[slides from SLP3 and Mohit lyyer]

# goal: assign probability to a piece of text

- why would we ever want to do this?
- translation:
  - P(i flew to the movies) <<<<< P(i went to the movies)</li>
- speech recognition:
  - P(i saw a van) >>>> P(eyes awe of an)
- text classification (NB):
  - P(i am so mad!! | [author is happy]) <</li>
     P(i am so mad!! | [author is not happy])

#### You use Language Models every day!

#### Probabilistic Language Modeling

 Goal: compute the probability of a sentence or sequence of words:

$$P(W) = P(W_1, W_2, W_3, W_4, W_5...W_n)$$

- Related task: probability of an upcoming word:

  P(w<sub>5</sub>|w<sub>1</sub>,w<sub>2</sub>,w<sub>3</sub>,w<sub>4</sub>)
- A model that computes either of these:

P(W) or  $P(w_n|w_1,w_2...w_{n-1})$  is called a language model or LM

#### How to compute P(W)

- How to compute this joint probability:
  - P(its, water, is, so, transparent, that)
- Intuition: let's rely on the Chain Rule of Probability

#### Reminder: The Chain Rule

Recall the definition of conditional probabilities

$$P(B|A) = P(A,B)/P(A)$$
 Rewriting:  $P(A,B) = P(A)P(B|A)$ 

More variables:

$$P(A,B,C,D) = P(A)P(B|A)P(C|A,B)P(D|A,B,C)$$

The Chain Rule in General

$$P(x_1,x_2,x_3,...,x_n) = P(x_1)P(x_2|x_1)P(x_3|x_1,x_2)...P(x_n|x_1,...,x_{n-1})$$

The Chain Rule applied to compute joint probability of words in sentence

$$P(w_1 w_2 ... w_n) = \prod_{i} P(w_i | w_1 w_2 ... w_{i-1})$$

P("its water is so transparent") =

 $P(its) \times P(water|its) \times P(is|its water)$ 

× P(so|its water is) × P(transparent|its water is so)

let's try one step!

#### How to estimate these probabilities

Could we just count and divide?

P(the | its water is so transparent that) =
Count(its water is so transparent that the)
Count(its water is so transparent that)

#### How to estimate these probabilities

Could we just count and divide?

P(the | its water is so transparent that) =

Count(its water is so transparent that the)

Count(its water is so transparent that)

- No! Too many possible sentences!
- We'll never see enough data for estimating these

#### Markov Assumption

Simplifying assumption:

 $P(\text{the }|\text{ its water is so transparent that}) \approx P(\text{the }|\text{ that})$ 

Or maybe

 $P(\text{the }|\text{ its water is so transparent that}) \approx P(\text{the }|\text{ transparent that})$ 

#### Markov Assumption

$$P(w_1 w_2 ... w_n) \approx \prod_i P(w_i | w_{i-k} ... w_{i-1})$$

 In other words, we approximate each component in the product

$$P(w_i | w_1 w_2 \dots w_{i-1}) \approx P(w_i | w_{i-k} \dots w_{i-1})$$

#### Simplest case: Unigram model

$$P(w_1 w_2 \dots w_n) \approx \prod_i P(w_i)$$

Some automatically generated sentences from a unigram model:

fifth, an, of, futures, the, an, incorporated, a, a, the, inflation, most, dollars, quarter, in, is, mass

thrift, did, eighty, said, hard, 'm, july, bullish

that, or, limited, the

#### **Approximating Shakespeare**

1 gram	<ul> <li>To him swallowed confess hear both. Which. Of save on trail for are ay device and rote life have</li> <li>Hill he late speaks; or! a more to leg less first you enter</li> </ul>
2 gram	<ul><li>-Why dost stand forth thy canopy, forsooth; he is this palpable hit the King Henry. Live king. Follow.</li><li>-What means, sir. I confess she? then all sorts, he is trim, captain.</li></ul>
3 gram	<ul><li>-Fly, and will rid me these news of price. Therefore the sadness of parting, as they say, 'tis done.</li><li>-This shall forbid it should be branded, if renown made it empty.</li></ul>
4 gram	<ul><li>-King Henry. What! I will go seek the traitor Gloucester. Exeunt some of the watch. A great banquet serv'd in;</li><li>-It cannot be but so.</li></ul>

#### N-gram models

- Can extend n-grams to higher n...
- N-gram models are surprisingly useful; state of the art for >50 years!
- But this is an insufficient model of language
  - Long-distance dependencies
  - Language is compositional

we're doing longer-distance language modeling near the end of this course

(preview: how did we get long-distance effects with syntax model?)

#### Estimating bigram probabilities

- The Maximum Likelihood Estimate (MLE)
  - relative frequency based on the empirical counts on a training set

$$P(w_{i} | w_{i-1}) = \frac{count(w_{i-1}, w_{i})}{count(w_{i-1})}$$

$$P(W_{i} \mid W_{i-1}) = \frac{C(W_{i-1}, W_{i})}{C(W_{i-1})}$$
c - count

#### An example

$$P(w_i \mid w_{i-1}) = \frac{C(w_{i-1}, w_i)}{C(w_{i-1})} \stackrel{ ~~\text{I am Sam }~~ }{ ~~\text{Sam I am }~~ }$$
  ~~I do not like green eggs and ham~~ 

$$P(I | ~~) = \frac{2}{3} = .67~~$$
  $P(Sam | ~~) = ???~~$   $P( | Sam) = \frac{1}{2} = 0.5$   $P(Sam | am) = ???$ 

#### An example

$$P(w_i \mid w_{i-1}) = \frac{c(w_{i-1}, w_i)}{c(w_{i-1})} \stackrel{ ~~\text{I am Sam }~~ }{ ~~\text{Sam I am }~~ }$$
  ~~I do not like green eggs and ham~~ 

$$P(I | ~~) = \frac{2}{3} = .67~~$$
  $P(Sam | ~~) = \frac{1}{3} = .33~~$   $P(am | I) = \frac{2}{3} = .67$   $P( | Sam) = \frac{1}{2} = 0.5$   $P(Sam | am) = \frac{1}{2} = .5$   $P(do | I) = \frac{1}{3} = .33$ 

#### A bigger example: Berkeley Restaurant Project sentences

- can you tell me about any good cantonese restaurants close by
- mid priced thai food is what i'm looking for
- tell me about chez panisse
- can you give me a listing of the kinds of food that are available
- i'm looking for a good place to eat breakfast
- when is caffe venezia open during the day

#### Raw bigram counts

#### • Out of 9222 sentences

	i	want	to	eat	chinese	food	lunch	spend
i	5	827	0	9	0	0	0	2
want	2	0	608	1	6	6	5	1
to	2	0	4	686	2	0	6	211
eat	0	0	2	0	16	2	42	0
chinese	1	0	0	0	0	82	1	0
food	15	0	15	0	1	4	0	0
lunch	2	0	0	0	0	1	0	0
spend	1	0	1	0	0	0	0	0

Raw bigram probabilities 
$$P(w_i | w_{i-1}) = \frac{c(w_{i-1}, w_i)}{c(w_{i-1})}$$

Normalize by unigrams:

• Result:	253

i	want	to	eat	chinese	food	lunch	spend
2533	927	2417	746	158	1093	341	278

	i	want	to	eat	chinese	food	lunch	spend
i	0.002	0.33	0	0.0036	0	0	0	0.00079
want	0.0022	0	0.66	0.0011	0.0065	0.0065	0.0054	0.0011
to	0.00083	0	0.0017	0.28	0.00083	0	0.0025	0.087
eat	0	0	0.0027	0	0.021	0.0027	0.056	0
chinese	0.0063	0	0	0	0	0.52	0.0063	0
food	0.014	0	0.014	0	0.00092	0.0037	0	0
lunch	0.0059	0	0	0	0	0.0029	0	0
spend	0.0036	0	0.0036	0	0	0	0	0

#### Bigram estimates of sentence probabilities

these probabilities get super tiny when we have longer inputs w/ more infrequent words... how can we get around this?

#### What kinds of knowledge?

```
P(english|want) = .0011

P(chinese|want) = .0065

P(to|want) = .66

grammar - infinitive verb

P(eat | to) = .28
P(food | to) = 0

P(want | spend) = 0
grammar

P(i | <s>) = .25
```

#### Evaluation

- Does the model give higher probability to real text?
  - ...in the test set (why?)

#### Intuition of Perplexity

- The Shannon Game: How well can we predict the next word? I always order pizza with cheese and The 33<sup>rd</sup> President of the US was \_\_\_\_\_ I saw a
- Unigrams are terrible at this game. (Why?)
- A better model of a text.
  - is one which assigns a higher probability to the word that actually occurs
  - compute per word log likelihood (M words, m test sentence  $s_i$ )

pepperoni 0.1 anchovies 0.01

mushrooms 0.1

Claude Shannon  $(1916 \sim 2001)$ 

fried rice 0.0001

and 1e-100

#### **Perplexity**

The best language model is one that best predicts an unseen test set

Gives the highest P(sentence)

Perplexity is the inverse probability of the test set, normalized by the number of words:

Chain rule:

For bigrams:

$$PP(W) = P(w_1 w_2 ... w_N)^{-\frac{1}{N}}$$
$$= N \frac{1}{M}$$

$$PP(W) = \sqrt[N]{\prod_{i=1}^{N} \frac{1}{P(w_i|w_1...w_{i-1})}}$$

$$PP(W) = \sqrt[N]{\prod_{i=1}^{N} \frac{1}{P(w_i|w_{i-1})}}$$

Minimizing perplexity is the same as maximizing probability

### Perplexity and log-likelihood

#### Lower perplexity = better model

 Training 38 million words, test 1.5 million words, Wall Street Journal

N-gram Order	Unigram	Bigram	Trigram
Perplexity	962	170	109

#### Perplexity as branching factor

Let's suppose a sentence consisting of random digits What is the perplexity of this sentence according to a model that assign P=1/10 to each digit?

$$PP(W) = P(w_1 w_2 ... w_N)^{-\frac{1}{N}}$$

$$= (\frac{1}{10}^N)^{-\frac{1}{N}}$$

$$= \frac{1}{10}^{-1}$$

$$= 10$$

#### N-gram sparsity (Shakespeare corpus)

- N=884,647 tokens, V=29,066
- Shakespeare produced 300,000 bigram types out of  $V^2$ = 844 million possible bigrams.
  - So 99.96% of the possible bigrams were never seen (have zero entries in the table)
- Quadrigrams worse: What's coming out looks like Shakespeare because it is Shakespeare

#### Zeros

#### Training set:

- ... denied the allegations
- ... denied the reports
- ... denied the claims
- ... denied the request

Test set

... denied the offer

... denied the loan

P("offer" | denied the) = 0

how does this affect perplexity?

#### The intuition of smoothing (from Dan Klein)

• When we have sparse statistics:

P(w | denied the)

3 allegations

2 reports

1 claims

1 request

7 total

P(w | denied the)

2.5 allegations

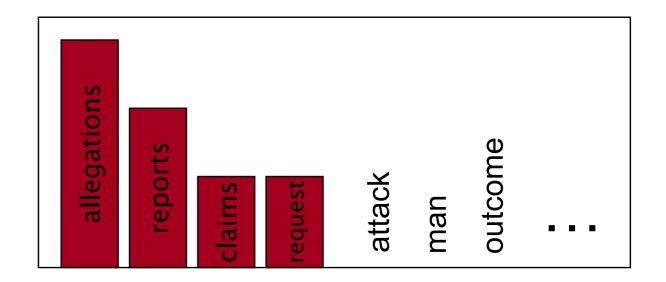

1.5 reports

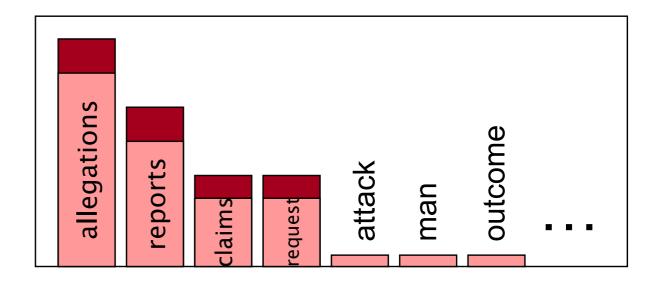

0.5 claims

0.5 request

2 other

7 total

#### Add-one estimation (again!)

- Also called Laplace smoothing
- Pretend we saw each word one more time than we did
- Just add one to all the counts!

$$P_{MLE}(w_i \mid w_{i-1}) = \frac{c(w_{i-1}, w_i)}{c(w_{i-1})}$$
 MLE estimate:

Add-1 estimate:

$$P_{Add-1}(w_i \mid w_{i-1}) = \frac{c(w_{i-1}, w_i) + 1}{c(w_{i-1}) + V}$$

## Berkeley Restaurant Corpus: Laplace smoothed bigram counts

	i	want	to	eat	chinese	food	lunch	spend
i	6	828	1	10	1	1	1	3
want	3	1	609	2	7	7	6	2
to	3	1	5	687	3	1	7	212
eat	1	1	3	1	17	3	43	1
chinese	2	1	1	1	1	83	2	1
food	16	1	16	1	2	5	1	1
lunch	3	1	1	1	1	2	1	1
spend	2	1	2	1	1	1	1	1

#### Laplace-smoothed bigrams

$$P^*(w_n|w_{n-1}) = \frac{C(w_{n-1}w_n) + 1}{C(w_{n-1}) + V}$$

	i	want	to	eat	chinese	food	lunch	spend
i	0.0015	0.21	0.00025	0.0025	0.00025	0.00025	0.00025	0.00075
want	0.0013	0.00042	0.26	0.00084	0.0029	0.0029	0.0025	0.00084
to	0.00078	0.00026	0.0013	0.18	0.00078	0.00026	0.0018	0.055
eat	0.00046	0.00046	0.0014	0.00046	0.0078	0.0014	0.02	0.00046
chinese	0.0012	0.00062	0.00062	0.00062	0.00062	0.052	0.0012	0.00062
food	0.0063	0.00039	0.0063	0.00039	0.00079	0.002	0.00039	0.00039
lunch	0.0017	0.00056	0.00056	0.00056	0.00056	0.0011	0.00056	0.00056
spend	0.0012	0.00058	0.0012	0.00058	0.00058	0.00058	0.00058	0.00058

#### Reconstituted counts

$$c^*(w_{n-1}w_n) = \frac{[C(w_{n-1}w_n) + 1] \times C(w_{n-1})}{C(w_{n-1}) + V}$$

	i	want	to	eat	chinese	food	lunch	spend
i	3.8	527	0.64	6.4	0.64	0.64	0.64	1.9
want	1.2	0.39	238	0.78	2.7	2.7	2.3	0.78
to	1.9	0.63	3.1	430	1.9	0.63	4.4	133
eat	0.34	0.34	1	0.34	5.8	1	15	0.34
chinese	0.2	0.098	0.098	0.098	0.098	8.2	0.2	0.098
food	6.9	0.43	6.9	0.43	0.86	2.2	0.43	0.43
lunch	0.57	0.19	0.19	0.19	0.19	0.38	0.19	0.19
spend	0.32	0.16	0.32	0.16	0.16	0.16	0.16	0.16

#### Compare with raw bigram counts

	i	want	to	eat	chinese	food	lunch	spend
i	5	827	0	9	0	0	0	2
want	2	0	608	1	6	6	5	1
to	2	0	4	686	2	0	6	211
eat	0	0	2	0	16	2	42	0
chinese	1	0	0	0	0	82	1	0
food	15	0	15	0	1	4	0	0
lunch	2	0	0	0	0	1	0	0
spend	1	0	1	0	0	0	0	0

	i	want	to	eat	chinese	food	lunch	spend
i	3.8	527	0.64	6.4	0.64	0.64	0.64	1.9
want	1.2	0.39	238	0.78	2.7	2.7	2.3	0.78
to	1.9	0.63	3.1	430	1.9	0.63	4.4	133
eat	0.34	0.34	1	0.34	5.8	1	15	0.34
chinese	0.2	0.098	0.098	0.098	0.098	8.2	0.2	0.098
food	6.9	0.43	6.9	0.43	0.86	2.2	0.43	0.43
lunch	0.57	0.19	0.19	0.19	0.19	0.38	0.19	0.19
spend	0.32	0.16	0.32	0.16	0.16	0.16	0.16	0.16

#### Add-1 estimation is a blunt instrument

- So add-1 isn't used for N-grams:
  - We'll see better methods
- But add-1 is used to smooth other NLP models
  - For text classification
  - In domains where the number of zeros isn't so huge.
