- Image: two-dimensional array of 'brightness' values.
- Geometry: where in an image a point will project.
- Radiometry: what the brightness of the point will be.
- Brightness: informal notion used to describe both scene and image brightness.
- Image brightness: related to energy flux incident on the image plane:

IRRADIANCE

Scene brightness: brightness related to energy flux emitted (radiated) from a surface.

RADIANCE

Computer Visior

- Electromagnetic energy
- Wave model
- Light sources typically radiate over a frequency spectrum
- Φ watts radiated into 4π radians

Irradiance

Light falling on a surface from all directions.
How much?

Irradiance: power per unit area falling on a surface.

Irradiance E =
$$\frac{d\Phi}{dA}$$
 watts/m²

Inverse Square Law

Relationship between radiance (radiant intensity) and irradiance

Radiance: power per unit foreshortened area emitted into a solid angle

$$L = \frac{d^2 \Phi}{dA_f d\omega}$$

(watts/m2 - steradian)

Pseudo-Radiance

Consider two definitions:

• Radiance:

power per unit foreshortened area emitted into a solid angle

• Pseudo-radiance

power per unit area emitted into a solid angle

- Why should we work with radiance rather than pseudoradiance?
 - Only reason: Radiance is more closely related to our intuitive notion of "brightness".

Lambertian Surfaces

- A particular point P on a Lambertian (perfectly matte) surface appears to have the same brightness no matter what angle it is viewed from.
 - Piece of paper
 - Matte paint
- Doesn't depend upon incident light angle.
- What does this say about how they emit light?

Area of black box = 1 Area of orange box = 1/cos(Theta) Foreshortening rule.

Lambertian Surfaces

Relative magnitude of light scattered in each direction. Proportional to cos (Theta).

Area of black box = 1 Area of orange box = 1/cos(Theta) Foreshortening rule.

Computer Visior

Geometry

Goal: Relate the radiance of a surface to the irradiance in the image plane of a simple optical system.

We need to determine $d\Phi$ and dA

• $E = d\Phi / dA_s$

Surface Irradiance: $E = R \cos i / r^2$

Reflections from a Surface II

Now treat small surface area as an emitter

•because it is bouncing light into the world

How much light gets reflected?

- E is the surface irradiance
- L is the surface radiance = luminance
- They are related through the surface reflectance function:

$$\frac{L_s}{E} = \rho(i,e,g,\lambda)$$

May also be a function of the wavelength of the light

 $L_{s} = \frac{d^{2}\Phi}{dA_{s}d\omega}$

Luminance of patch (known from previous step)

What is the power of the surface patch as a source in the direction of the lens?

$$d^2\Phi = L_s dA_s d\omega$$

Introduction to

Computer Vision

Through a Lens Darkly

In general:

- L_s is a function of the angles i and e.
- Lens can be quite large
- Hence, must integrate over the lens solid angle to get $d\Phi$

$$d\Phi = dA_s \int_{\Omega} L_s d\Omega$$

Introduction to

Lens diameter is small relative to distance from patch

$$d\Phi = dA_{s} \int L_{s} d\Omega$$

= dA_{s} cos e L_{s} $\frac{\pi (d/2)^{2} cos \alpha}{(z / cos \alpha)^{2}}$

Power concentrated in lens:

$$d\Phi = \frac{\pi}{4} L_s dA_s \left[\frac{d}{Z}\right]^2 \cos e \cos^3 \alpha$$

Assuming a lossless lens, this is also the power radiated by the lens as a source.

$$\frac{dA_{s}\cos e}{(Z/\cos \alpha)^{2}} = \frac{dA_{i}\cos \alpha}{(-f/\cos \alpha)^{2}} \qquad \qquad \frac{dA_{s}}{dA_{i}} = \frac{\cos \alpha}{\cos e} \left(\frac{Z}{-f}\right)^{2}$$

Introduction to

Computer Vision

The Fundamental Result

Source Radiance to Image Sensor Irradiance:

$$\frac{dA_{s}}{dA_{i}} = \frac{\cos \alpha}{\cos e} \left(\frac{Z}{-f}\right)^{2}$$

$$E_i = L_s \frac{dA_s}{dA_i} \frac{\pi}{4} \left[\frac{d}{Z}\right]^2 \cos e \cos \frac{3}{\alpha}$$

$$E_{i} = L_{s} \frac{\cos \alpha}{\cos e} \left(\frac{Z}{-f}\right)^{2} \frac{\pi}{4} \left(\frac{d}{Z}\right)^{2} \cos e \cos \frac{3}{\alpha}$$

$$E_{i} = L_{s} \frac{\pi}{4} \left[\frac{d}{-f}\right]^{2} \cos^{4}\alpha$$

Introduction to

Radiometry Final Result

$$E_{i} = L_{s} \frac{\pi}{4} \left[\frac{d}{-f}\right]^{2} \cos^{4}\alpha$$

Image irradiance is a function of:

- Scene radiance L_s
- Focal length of lens f
- Diameter of lens d
 - f/d is often called the 'effective focal length' of the lens
- \bullet Off-axis angle α
