**Conditional Independence**

- **Notation**: $x_A \perp x_B | x_C$
  
  **Definition**: two (sets of) variables $x_A$ and $x_B$ are conditionally independent given a third $x_C$ if:
  
  $$P(x_A, x_B | x_C) = P(x_A | x_C)P(x_B | x_C) \quad \forall x_C$$
  
  which is equivalent to saying
  
  $$P(x_A | x_B, x_C) = P(x_A | x_C) \quad \forall x_C$$

- Only a subset of all distributions respect any given (nontrivial) conditional independence statement. The subset of distributions that respect all the CI assumptions we make is the family of distributions consistent with our assumptions.

- Probabilistic graphical models are a powerful, elegant and simple way to specify such a family.
• Probabilistic graphical models represent large joint distributions compactly using a set of “local” relationships specified by a graph.

• Each random variable in our model corresponds to a graph node.

• There are directed/undirected *edges* between the nodes which tell us qualitatively about the *factorization* of the joint probability.

• There are *functions* stored at the nodes which tell us the quantitative details of the pieces into which the distribution factors.

• Graphical models are also known as Bayes(ian) (Belief) Net(work)s.
Directed Graphical Models

- Consider *directed acyclic graphs* over \( n \) variables.
- Each node has (possibly empty) set of parents \( \pi_i \).
- Each node maintains a function \( f_i(x_i; x_{\pi_i}) \) such that \( f_i > 0 \) and \( \sum_{x_i} f_i(x_i; x_{\pi_i}) = 1 \) \( \forall \pi_i \).
- Define the joint probability to be:

\[
P(x_1, x_2, \ldots, x_n) = \prod_i f_i(x_i; x_{\pi_i})
\]

Even with no further restriction on the the \( f_i \), it is always true that

\[
f_i(x_i; x_{\pi_i}) = P(x_i| x_{\pi_i})
\]

so we will just write

\[
P(x_1, x_2, \ldots, x_n) = \prod_i P(x_i| x_{\pi_i})
\]

- Factorization of the joint in terms of *local conditional probabilities*. Exponential in “fan-in” of each node instead of in total variables \( n \).
Example DAG

- Consider this six node network:

```
  X_1 --> X_2 --> X_4
  |       |       |
  |       V       |
  X_3 --> X_5 --> X_6
```

The joint probability is now:

\[
P(x_1, x_2, x_3, x_4, x_5, x_6) = P(x_1)P(x_2|x_1)P(x_3|x_1)
\]
\[
P(x_4|x_2)P(x_5|x_3)P(x_6|x_2, x_5)
\]
Key point about directed graphical models:

*Missing edges imply conditional independence*

Remember, that by the chain rule we can always write the full joint as a product of conditionals, given an ordering:

\[ P(x_1, x_2, x_3, x_4, \ldots) = P(x_1)P(x_2|x_1)P(x_3|x_1, x_2)P(x_4|x_1, x_2, x_3) \ldots \]

If the joint is represented by a DAGM, then some of the conditioned variables on the right hand sides are missing. This is equivalent to enforcing conditional independence.

Start with the “idiot’s graph”: each node has all previous nodes in the ordering as its parents.

Now remove edges to get your DAG.

Removing an edge into node \( i \) eliminates an argument from the conditional probability factor \( p(x_i|x_1, x_2, \ldots, x_{i-1}) \)
Information Extraction: Coreference and Relation Extraction

Lecture #20

Computational Linguistics

University of Massachusetts Amherst

Andrew McCallum
What is “Information Extraction”

As a family of techniques:

Information Extraction = segmentation + classification + association + clustering

October 14, 2002, 4:00 a.m. PT

For years, Microsoft Corporation CEO Bill Gates railed against the economic philosophy of open-source software with Orwellian fervor, denouncing its communal licensing as a "cancer" that stifled technological innovation.

Today, Microsoft claims to "love" the open-source concept, by which software code is made public to encourage improvement and development by outside programmers. Gates himself says Microsoft will gladly disclose its crown jewels—the coveted code behind the Windows operating system—to select customers.

"We can be open source. We love the concept of shared source," said Bill Veghte, a Microsoft VP. "That's a super-important shift for us in terms of code access."

Richard Stallman, founder of the Free Software Foundation, countered saying...

Queen Elizabeth set about transforming her husband, King George VI, into a viable monarch. Logue, a renowned speech therapist, was summoned to help the King overcome his speech impediment...
SAN SALVADOR, 15 JAN 90 (ACAN-EFE) -- [TEXT] ARMANDO CALDERON SOL, PRESIDENT OF THE NATIONALIST REPUBLICAN ALLIANCE (ARENA), THE RULING SALVADORAN PARTY, TODAY CALLED FOR AN INVESTIGATION INTO ANY POSSIBLE CONNECTION BETWEEN THE MILITARY PERSONNEL IMPLICATED IN THE ASSASSINATION OF JESUIT PRIESTS.

"IT IS SOMETHING SO HORRENDOUS, SO MONSTROUS, THAT WE MUST INVESTIGATE THE POSSIBILITY THAT THE FMLN (FARABUNDO MARTI NATIONAL LIBERATION FRONT) STAGED THESE MURDERS TO DISCREDIT THE GOVERNMENT," CALDERON SOL SAID.

SALVADORAN PRESIDENT ALFREDO CRISTIANI IMPLICATED FOUR OFFICERS, INCLUDING ONE COLONEL, AND FIVE MEMBERS OF THE ARMED FORCES IN THE ASSASSINATION OF SIX JESUIT PRIESTS AND TWO WOMEN ON 16 NOVEMBER AT THE CENTRAL AMERICAN UNIVERSITY.
Why It’s Hard

Many sources of information play a role

- head noun matches
  - IBM *executives* = the *executives*

- syntactic constraints
  - John helped himself to...
  - John helped him to...

- number and gender agreement
- discourse focus, recency, syntactic parallelism, semantic class, world knowledge, …
Why It’s Hard

• No single source is a completely reliable indicator
  – number agreement
    • the assassination = these murders
• Identifying each of these features automatically, accurately, and in context, is hard
• Coreference resolution subsumes the problem of pronoun resolution…
A Machine Learning Approach

• Classification
  – given a description of two noun phrases, \( NP_i \) and \( NP_j \), classify the pair as coreferent or not coreferent

[Queen Elizabeth] set about transforming [her] [husband], ...

not coref ?

Aone & Bennett [1995]; Connolly et al. [1994]; McCarthy & Lehnert [1995]; Soon et al. [2001]; Ng & Cardie [2002]; …
A Machine Learning Approach

- Clustering
  - coordinates pairwise coreference decisions

[Queen Elizabeth], set about transforming [her] [husband] ...

Queen Elizabeth
Queen Elizabeth her

King George VI
husband
King George VI the King
his

Logue
a renowned speech therapist

not coref
not coref
not coref

Clustering Algorithm
Machine Learning Issues

• Training data creation
• Instance representation
• Learning algorithm
• Clustering algorithm
Training Data Creation

• Creating training instances
  – texts annotated with coreference information
  – one instance \( \text{inst}(NP_i, NP_j) \) for each pair of NPs
    • assumption: \( NP_i \) precedes \( NP_j \)
    • feature vector: describes the two NPs and context
    • class value:
      \[
      \begin{align*}
      \text{coref} & \quad \text{pairs on the same coreference chain} \\
      \text{not coref} & \quad \text{otherwise}
      \end{align*}
      \]
Instance Representation

- 25 features per instance
  - lexical (3)
    - string matching for pronouns, proper names, common nouns
  - grammatical (18)
    - pronoun, demonstrative (the, this), indefinite (it is raining), …
    - number, gender, animacy
    - appositive (george, the king), predicate nominative (a horse is a mammal)
    - binding constraints, simple contra-indexing constraints, …
    - span, maximalnp, …
  - semantic (2)
    - same WordNet class
    - alias
  - positional (1)
    - distance between the NPs in terms of # of sentences
  - knowledge-based (1)
    - naïve pronoun resolution algorithm
Learning Algorithm

• RIPPER (Cohen, 1995)
  C4.5 (Quinlan, 1994)
  – rule learners
    • input: set of training instances
    • output: coreference classifier

• Learned classifier
  • input: test instance (represents pair of NPs)
  • output: classification
    confidence of classification
Clustering Algorithm

- **Best-first single-link clustering**
  - Mark each $NP_j$ as belonging to its own class: $NP_j \in c_j$
  - Proceed through the NPs in left-to-right order.
    - For each NP, $NP_j$, create test instances, $inst(NP_i, NP_j)$, for all of its preceding NPs, $NP_i$.
    - Select as the antecedent for $NP_j$ the highest-confidence coreferent NP, $NP_i$, according to the coreference classifier (or none if all have below .5 confidence);
      Merge $c_j$ and $c_j$. 
Evaluation

- MUC-6 and MUC-7 coreference data sets
- Documents annotated w.r.t. coreference
- 30 + 30 training texts (dry run)
- 30 + 20 test texts (formal evaluation)
- Scoring program
  - Recall
  - Precision
  - F-measure: $2PR/(P+R)$

</tbody>
</table>
Problem 1

• Coreference is a rare relation
  – skewed class distributions (2% positive instances)
  – *remove some negative instances*

farthest antecedent
Problem 2

• Coreference is a discourse-level problem
  – different solutions for different types of NPs
    • proper names: string matching and aliasing
  – inclusion of “hard” positive training instances
  – *positive example selection*: selects easy positive training instances (cf. Harabagiu *et al.* (2001))

Queen Elizabeth set about transforming her *husband*, King George VI, into a viable monarch. *Logue,* the renowned speech therapist, was summoned to help the King overcome his speech impediment...
Problem 3

- Coreference is an equivalence relation
  - loss of transitivity
  - need to tighten the connection between classification and clustering
  - prune learned rules w.r.t. the clustering-level coreference scoring function

[Queen Elizabeth] set about transforming [her] [husband], ...

not coref?

The Citation Clustering Data

- Over 1,000,000 citations
- About 100,000 unique papers
- About 100,000 unique vocabulary words
- Over 1 trillion distance calculations
The Canopies Approach

- Two distance metrics: cheap & expensive
- First Pass
  - very inexpensive distance metric
  - create overlapping canopies
- Second Pass
  - expensive, accurate distance metric
  - canopies determine which distances calculated
Illustrating Canopies
Overlapping Canopies
Creating canopies with two thresholds

- Put all points in D
- Loop:
  - Pick a point X from D
  - Put points within $K_{\text{loose}}$ of X in canopy
  - Remove points within $K_{\text{tight}}$ of X from D
Using canopies with Greedy Agglomerative Clustering

- Calculate expensive distances between points in the same canopy
- All other distances default to infinity
- Sort finite distances and iteratively merge closest
Computational Savings

• inexpensive metric \(<<\) expensive metric
• \# canopies per data point: \(f\) (small, but \(>1\))
• number of canopies: \(c\) (large)

• complexity reduction:

\[ O\left(\frac{f^2}{c}\right) \]
The Experimental Dataset

- All citations for authors:
  - Michael Kearns
  - Robert Schapire
  - Yoav Freund
- 1916 citations
- 121 unique papers
- Similar dataset used for parameter tuning
Inexpensive Distance Metric for Text

- Word-level matching (TFIDF)
- Inexpensive using an inverted index
Expensive Distance Metric for Text

- String edit distance
- Compute with Dynamic Programming
- Costs for character:
  - insertion
  - deletion
  - substitution
  - ...

Hi [PERSON Ted] and [PERSON Hill],

Just a reminder that the game move will need to be entered [TIME tonight]. We will need data on operations, raw materials ordering, and details of the bond to be sold.

[PERSON Hill]: I will be in the [LOCATION lobby] after the class at [TIME 9 pm]. How about we meet in the [LOCATION lobby] around that time (i.e. when both our classes are over).

[PERSON Ted]: Let me know how you are going to provide the bond related input information. We can either meet in the [LOCATION lobby] around [TIME 5.30 pm] or you can e-mail me the info.

Thanks, [PERSON Ajay]

Relationship Extraction

[Miller et. al, 2000]

An example:

Donald M. Goldstein, a historian at the University of Pittsburgh . . .

- Entity information to be extracted:
  - Named entity boundaries:
    Organizations, people, and locations
  - Person descriptors: “a historian at the University of Pittsburgh” refers to “Donald M. Goldstein”

- Entity relationships to be extracted:
  - Employer/Employee relations
    (e.g., Goldstein is employed at University of Pittsburgh)
  - Company/product relations
  - Organization/headquarters-location relation
Relationship Extraction: Annotation

Another example:

Nance, who is a paid consultant to ABC News, said . . .

- The following information was annotated:
  - *Nance* as a person; *ABC News* as an organization; *a paid consultant to ABC News* as a descriptor
  - A *coreference* link between *Nance* and *a paid consultant to ABC News*
  - An *employer-relation* link from *a paid consultant to ABC News* to *ABC News*

Next question: how can we build a model which recovers this information?
The Basic Approach

- Build a statistical parsing model which simultaneously recovers syntactic relation and the information extraction information

To do this:

- Step 1: annotate training sentences for entities, descriptors, coreference links, and relation links

- Step 2: train a parser on the Penn treebank, and apply it to the new training sentences. **Force the parser to produce parses that are consistent with the entity/descriptor etc. boundaries**

- Step 3: enhance the parse trees to include the information extraction information (we’ll come to this soon)

- Step 4: **re-train** the parser on the new training data, and with the new annotations
Nance is a paid consultant to ABC News.
Add semantic tags showing named entities

org = organization, per = person, org-r = organization “reportable” (complete), per-r = person “reportable” (complete)
Add semantic tags showing descriptors

per-desc = person descriptor,

per-desc-r = person descriptor “reportable” (complete)
Add semantic tags showing link between “Nancy” and the descriptor
per-desc-of = person/descriptor link, per-desc-ptr = person/descriptor pointer
Add link showing employee-employer relation
emp-of = employee-of link, emp-ptr = employee-of pointer

PERSON entity, PERSON descriptor link, DESCRIPTOR, EMPLOYER-OF relation, ORG entity
Building a Parser

- We now have context-free rules where each non-terminal in the grammar has
  - A syntactic category
  - A semantic label
  - A head-word/head-tag

It’s possible to modify syntactic parsers to estimate rule probabilities in this case
Summary

- Goal: build a parser that recovers syntactic structure, named entities, descriptors, and relations

- Annotation: mark entity boundaries, descriptor boundaries, links between entities and descriptors

- Enriched parse trees: given annotation, and a parse tree, form a new enriched parse tree

- The statistical model: non-terminals now include syntactic category, semantic label, head word, head tag. Rule probabilities are estimated using similar methods to syntactic parsers

- Results: precision = 81%, recall = 64% in recovering relations (employer/employee, company/product, company/headquarters-location)
Main Points

Co-reference
- How to cast as classification [Cardie]
- Measures of string similarity [Cohen]
- Scaling up [McCallum et al]

Relation extraction
- With augmented grammar [Miller et al 2000]
- With joint inference [Roth & Yih]
- Semi-supervised [Brin]
(1) Association with Graphical Models

Capture arbitrary-distance dependencies among predictions.

Random variable over the class of relation between entity #2 and #1, e.g. over {lives-in, is-boss-of, ...}

Local language models contribute evidence to relation classification.

Dependencies between classes of entities and relations!

Inference with loopy belief propagation.
(1) **Association with Graphical Models**

Also capture long-distance dependencies among predictions.

Local language models contribute evidence to entity classification.

Random variable over the class of entity #1, e.g. over \{person, location,...\}

Local language models contribute evidence to relation classification.

Random variable over the class of relation between entity #2 and #1, e.g. over \{lives-in, is-boss-of,...\}

Dependencies between classes of entities and relations!

Inference with loopy belief propagation.
Association with Graphical Models

Also capture long-distance dependencies among predictions.

Local language models contribute evidence to entity classification.

Random variable over the class of entity #1, e.g. over \{person, location,\ldots\}

Random variable over the class of relation between entity #2 and #1, e.g. over \{lives-in, is-boss-of,\ldots\}

Local language models contribute evidence to relation classification.

Dependencies between classes of entities and relations!

Inference with loopy belief propagation.

[Roth & Yih 2002]

Relation extraction
• With augmented grammar [Miller et al 2000]
• With joint inference [Roth & Yih]
• Semi-supervised [Brin]
Partially Supervised Approaches to Relation Extraction

- Last lecture: introduced a partially supervised method for named entity classification

- Basic observation: “redundancy” in that either spelling or context of an entity is often sufficient to determine its type

- Lead to cotraining approaches, where two classifiers bootstrap each other from a small number of seed rules

- Can we apply these kind of methods to relation extraction?
From [Brin, 1998]

The World Wide Web provides a vast source of information of almost all types, ranging from DNA databases to resumes to lists of favorite restaurants. However, this information is often scattered among many web servers and hosts using many different formats. If these chunks of information could be extracted from the World Wide Web and integrated into a structure form, they would form an unprecedented source of information. It would include the largest international directory of people, the largest and most diverse databases of products, the greatest bibliography of academic works, and many other useful resources.
From [Brin, 1998]

For data we used a repository of 24 million web pages totalling 147 gigabytes. This data is part of the Stanford WebBase and is used for the Google search engine [BP], and other research projects. As a part of the search engine, we have built an inverted index of the entire repository.

The repository spans many disks and several machines. It takes a considerable amount of time to make just one pass over the data even without doing any substantial processing. Therefore, in these [sic] we only made passes over subsets of the repository on any given iteration.

http://google.stanford.edu
• From [Brin, 1998]:
  authors/book-titles, data = web data, seeds are

<table>
<thead>
<tr>
<th>Name</th>
<th>Book Title</th>
</tr>
</thead>
<tbody>
<tr>
<td>Isaac Asimov</td>
<td>The Robots of Dawn</td>
</tr>
<tr>
<td>David Brin</td>
<td>Startide Rising</td>
</tr>
<tr>
<td>James Gleik</td>
<td>Chaos: Making a New Science</td>
</tr>
<tr>
<td>Charles Dickens</td>
<td>Great Expectations</td>
</tr>
<tr>
<td>William Shakespeare</td>
<td>The Comedy of Errors</td>
</tr>
</tbody>
</table>
A pattern is a 5 tuple:

- **Order**: author preceding title, or visa versa
- **URL-prefix**: a prefix of the URL of the page of the pattern
- **prefix**: up to 10 characters preceding the author/title pair
- **middle**: the characters between the author and title
- **suffix**: up to 10 characters following the author/title pair
DIPRE: Inducing Patterns from Data

- Find all instances of seeds on web pages.
  Basic question: how do we induce patterns from these examples?
• Answer = Following procedure:

1. Group all occurrences together which have the same values for order, middle
2. For any group: Set url-prefix to be longest common prefix of the group’s URLs, prefix to be the longest common prefix of the group, suffix to be the longest common suffix
3. For each group’s pattern, calculate its specificity as

   \[ \text{spec}(p) = n|\text{middle}||\text{url-prefix}||\text{prefix}||\text{suffix}| \]

   where \( n \) is the number of examples in the group, \( |x| \) is the length of \( x \) in characters
4. If specificity exceeds some threshold, include the pattern
5. Else If all patterns occur on same webpage, reject the pattern
6. Else create new sub-groups grouped by characters in the urls which is one past url-prefix, and repeat the procedure in step 2 for these new sub-groups.
The Overall Algorithm

1. Use the seed examples to label some data

2. Induce patterns from the labeled examples, using method described on the previous slide

3. Apply the patterns to data, to get a new set of author/title pairs

4. Return to step 2, and iterate
DIPRE: Inducing Patterns from Data

The patterns found in the first iteration:

- The 5 seeds produced 199 labeled instances, giving the 3 patterns above
- Applying the three patterns gave 4047 new book instances
- Searching 5 million web pages gave 3972 occurrences of these books
- This gave 105 patterns, 24 applied to more than one URL
- Applied to 2 million URLs produced 9369 unique (author,title) pairs
- Manual intervention: removed 242 “bogus” items where the author was “Conclusion”
- Final iteration: ran over 156,000 documents which contained the word “books”; induced 346 patterns, 15,257 (author,title) pairs
(1) Association using Parse Tree

Simultaneously POS tag, parse, extract & associate!  [Miller et al 2000]

Increase space of parse constitutes to include entity and relation tags

<table>
<thead>
<tr>
<th>Notation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>$c_h$</td>
<td>head constituent category</td>
</tr>
<tr>
<td>$c_m$</td>
<td>modifier constituent category</td>
</tr>
<tr>
<td>$X_p$</td>
<td>$X$ of parent node</td>
</tr>
<tr>
<td>$t$</td>
<td>POS tag</td>
</tr>
<tr>
<td>$w$</td>
<td>word</td>
</tr>
</tbody>
</table>

Parameters e.g.

- $P(c_h|c_p)$
- $P(c_m|c_p,c_{hp},c_{m-1},w_p)$
- $P(t_m|c_m,t_h,w_h)$
- $P(w_m|c_m,t_m,t_h,w_h)$

(This is also a great example of extraction using a tree model.)
