

# COMPSCI 311: Introduction to Algorithms

## Lecture 7: Greedy Algorithms

Dan Sheldon

University of Massachusetts Amherst

# Greedy Algorithms

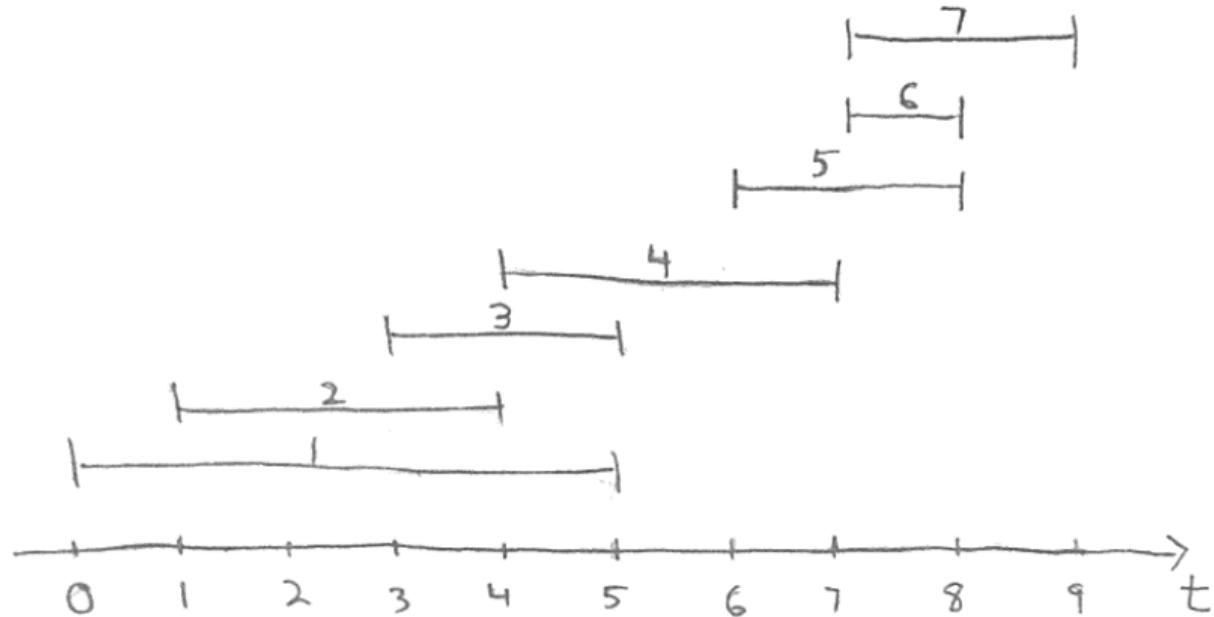

We are moving on to our study of algorithm design techniques:

- ▶ **Greedy**
- ▶ Divide-and-conquer
- ▶ Dynamic programming
- ▶ Network flow

Let's jump right in, then characterize later what it means to be "greedy".

## Interval Scheduling

- In the 80s, you could only watch a given TV show at the time it was broadcast. You want to watch the highest number of shows. Which subset of shows do you pick?

# Formalizing Interval Scheduling

Let's formalize the problem

- ▶ Shows  $1, 2, \dots, n$  (more generally: *requests* to be fulfilled with a given resource)
- ▶  $s_j$ : start time of show  $j$
- ▶  $f_j$ , also written  $f(j)$ : finish time of show  $j$
- ▶ Shows  $i$  and  $j$  are **compatible** if they don't overlap.
- ▶ Set  $A$  of shows is **compatible** if all pairs in  $A$  are compatible.
- ▶ Set  $A$  of shows is **optimal** if it is compatible and no other compatible set is larger.

**Goal:** find optimal set of shows

## Greedy Algorithms

- ▶ Main idea in greedy algorithms is to make one choice at a time in a “greedy” fashion. (Choose the thing that looks best, never look back...)
- ▶ We will sort shows in some “natural order” and choose shows one by one if they’re compatible with the shows already chosen.

Concretely:

$R \leftarrow$  set of all shows **sorted by some property**

$A \leftarrow \{\}$

▷ selected shows

**while**  $R$  is not empty **do**

    take first show  $i$  from  $R$

    add  $i$  to  $A$

    delete  $i$  and all overlapping shows from  $R$

## Clicker

$R \leftarrow$  set of all shows **sorted by some property**

$A \leftarrow \{\}$

▷ selected shows

**while**  $R$  is not empty **do**

    take first show  $i$  from  $R$

    add  $i$  to  $A$

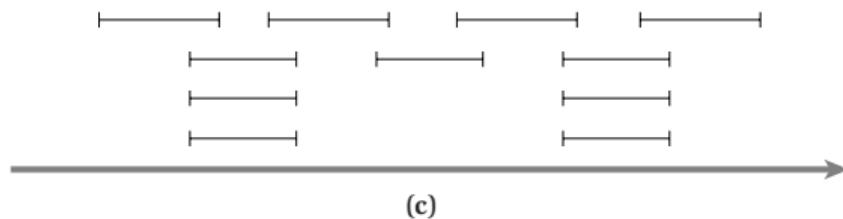

    delete  $i$  and all overlapping shows from  $R$

Suppose an algorithm includes a step that sorts an  $n$  items. Then its running time is:

- A.  $O(n \log n)$
- B.  $\Omega(n \log n)$
- C.  $\Theta(n \log n)$
- D. None of the above

## What's a “natural order” ?

- ▶ *Start Time*: Consider shows in ascending order of  $s_j$ ?  
Not optimal in running example.
- ▶ *Shortest Time*: Consider shows in ascending order of  $f_j - s_j$ ?  
Not optimal in running example.
- ▶ *Fewest Conflicts*: Let  $c_j$  be number of shows which overlap with show  $j$ . Consider shows in ascending order of  $c_j$ .  
Optimal in running example. But not this one:

- ▶ *Finish Time*: Consider shows in ascending order of  $f_j$ .  
We'll show that this is always optimal!

## Analysis

Let  $A$  be the set of shows returned by the algorithm when shows are sorted by finish time. What do we need to prove?

- ▶  $A$  is compatible (obvious property of algorithm)
- ▶  $A$  is optimal

We will prove  $A$  is optimal by a “greedy stays ahead” argument

## Ordering by Finish Time is Optimal: “Greedy Stays Ahead”

- ▶ Let  $A = i_1, \dots, i_k$  be the intervals selected by the greedy algorithm
- ▶ Let  $O = j_1, \dots, j_m$  be the intervals of some optimal solution  $O$
- ▶ Assume both are sorted by finish time

A: |---i<sub>1</sub>---| |---i<sub>2</sub>---| ... |---i<sub>k</sub>---|

O: |---j<sub>1</sub>---| |---j<sub>2</sub>---| ... |---j<sub>m</sub>---|

- ▶ Could it be the case that  $m > k$ ?
- ▶ Observation:  $f(i_1) \leq f(j_1)$ . The first show in  $A$  finishes no later than the first show in  $O$ .
- ▶ **Claim** (“greedy stays ahead”):  $f(i_r) \leq f(j_r)$  for all  $r = 1, 2, \dots$   
The  $r$ th show in  $A$  finishes no later than the  $r$ th show in  $O$ .

## “Greedy Stays Ahead”

- ▶ **Claim:**  $f(i_r) \leq f(j_r)$  for all  $r = 1, 2, \dots$
- ▶ **Proof** by induction on  $r$
- ▶ **Base case** ( $r = 1$ ):  $i_r$  is the first choice of the greedy algorithm, which has the earliest overall finish time, so  $f(i_r) \leq f(j_r)$

## Induction Step

- ▶ Assume inductively that  $f(i_{r-1}) \leq f(j_{r-1})$  ( $r \geq 2$ )

A: |--i<sub>1</sub>--| ... |---i<sub>(r-1)</sub>---

O: |---j<sub>1</sub>---| ... |---j<sub>(r-1)</sub>---| |----j<sub>r</sub>----

- ▶  $j_r$  is compatible with  $j_{r-1}$ , so  $s(j_r) \geq f(j_{r-1})$
- ▶  $f(j_{r-1}) \geq f(i_{r-1})$  by inductive hypothesis
- ▶ Thus,  $s(j_r) \geq f(i_{r-1})$  and interval  $j_r$  is in the set of available intervals when trying to select  $i_r$
- ▶ Since we greedily select the earliest finish time,  $f(i_r) \leq f(j_r)$ , completing the inductive step

## Clicker

A: |---i<sub>1</sub>---| |---i<sub>2</sub>---| ... |---i<sub>k</sub>---|

O: |---j<sub>1</sub>---| |---j<sub>2</sub>---| ... |---j<sub>m</sub>---|

Recall that  $k$  is the number of intervals in the greedy solution and  $m$  is the number of intervals in an optimal solution. What have we just proven?

- A.  $f(i_r) \leq f(j_r)$  for  $r = 1, 2, \dots, m$
- B.  $f(i_r) \leq f(j_r)$  for  $r = 1, 2, \dots, k$
- C. The greedy algorithm is optimal.
- D. None of the above.

## Optimality

A: |--i<sub>1</sub>--| |--i<sub>2</sub>--| ... |--i<sub>k</sub>--|

O: |---j<sub>1</sub>---| |---j<sub>2</sub>---| ... |---j<sub>k</sub>---| ... |---j<sub>m</sub>---|

Can it be the case that  $k < m$ ?

No. Because “greedy stays ahead”, intervals  $j_{k+1}$  through  $j_m$  would be compatible with the greedy solution, and the greedy algorithm would not terminate until adding them.

## Running Time?

$R \leftarrow$  set of all shows **sorted by finishing time**

$A \leftarrow \{\}$

**while**  $R$  is not empty **do**

    take first show  $i$  from  $R$

    add  $i$  to  $A$

    delete  $i$  and all overlapping shows from  $R$

$\triangleright O(n) ?$

Can we make loop better than  $n^2$ ?

## Running Time?

$R \leftarrow$  set of all shows **sorted by finishing time**

$A \leftarrow \{\}, \text{end} = 0$

▷ most recent end time

**for** show  $i$  from 1 to  $n$  **do**

**if**  $s_i \geq \text{end}$  **then**

        add  $i$  to  $A$ ;  $\text{end} = f_i$

▷  $O(1)$

$\Theta(n \log n)$  — dominated by sort

# Algorithm Design—Greedy

Greedy: make a single “greedy” choice at a time, don’t look back.

## Learning goals:

---

Greedy	
Formulate problem	
Design algorithm	
Prove correctness	✓
Analyze running time	
Specific algorithms	Dijkstra, MST

---

Focus is on proof techniques. Next: another proof technique.
