Bayesian Networks: Parameters

The default parameterization in a discrete Bayesian network simply uses a separate parameter for each element of each CPT:

$$P_\theta(X=x|\mathbf{X}_{\text{pa}(X)}=\mathbf{y}) = \theta_{x|\mathbf{y}}^X$$

Bayesian Networks: Parameters

HD	G	BP	C	$P(HD G, BP, C)$

Yes	M	Low	Low	$\theta_{Y M,L,L}^{HD}$
No	F	Low	Low	$\theta_{N F,L,L}^{HD}$
Yes	F	Low	Low	$\theta_{Y F,L,L}^{HD}$
⋮	⋮	⋮	⋮	⋮

Today's Problem

- ▶ How do we choose the parameter values for a Bayesian network given a data set?
- ▶ The *maximum likelihood estimate* for $\theta_{x|\mathbf{y}}^X$ is just the number of times X takes value x when its parents take value \mathbf{y} , divided by the number of times its parents take the value \mathbf{y} :

$$P_\theta(X=x|\mathbf{Y}=\mathbf{y}) = \theta_{x|\mathbf{y}}^X = \frac{\#(X=x, \mathbf{Y}=\mathbf{y})}{\#(\mathbf{Y}=\mathbf{y})}$$

How can we derive this result?

Example: Smoker and Cancer

Maximum-Likelihood Estimation (MLE)

A parametric model $\{p_\theta | \theta \in \Theta\}$ is a family of probability distributions indexed by parameters θ

Given data $\mathbf{x}^{(1)}, \dots, \mathbf{x}^{(N)}$, how do we choose p_θ ? (Notation: $\mathbf{x}^{(n)} = (x_1^{(n)}, \dots, x_d^{(n)})$)

Principle of maximum likelihood: choose the distribution that assigns the highest probability to the data

11 / 29

Maximum-Likelihood Estimation (MLE)

For an observed value \mathbf{x} , the **log-likelihood** is

$$\mathcal{L}(\theta | \mathbf{x}) = \log p_\theta(\mathbf{x})$$

For a data set $\mathbf{x}^{(1:N)} = (\mathbf{x}^{(1)}, \dots, \mathbf{x}^{(N)})$, the log-likelihood is

$$\mathcal{L}(\theta | \mathbf{x}^{(1:N)}) = \frac{1}{N} \sum_{n=1}^N \log p_\theta(\mathbf{x}^{(n)})$$

Goal: find θ to maximize $\mathcal{L}(\theta | \mathbf{x}^{(1:N)})$

12 / 29

Example: Bernoulli Model

Suppose $x^{(1)}, x^{(2)}, \dots, x^{(N)}$ are drawn from a Bernoulli distribution:

$$p_\theta(x) = \begin{cases} 1 - \theta, & x = 0 \\ \theta, & x = 1 \end{cases}$$

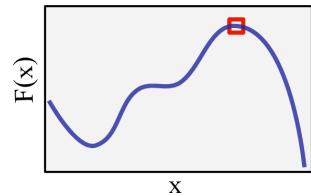

The log-likelihood is

$$\begin{aligned} \mathcal{L}(\theta | \mathbf{x}^{(1:N)}) &= \frac{1}{N} \sum_{n=1}^N \log p_\theta(x^{(n)}) \\ &= \frac{1}{N} \sum_{n=1}^N (\mathbb{I}[x^{(n)} = 0] \log(1 - \theta) + \mathbb{I}[x^{(n)} = 1] \log \theta) \\ &= \frac{\#(X = 0)}{N} \log(1 - \theta) + \frac{\#(X = 1)}{N} \log \theta. \end{aligned}$$

Learning as Likelihood Maximization

How can we find the model parameters θ that maximize the likelihood?

- ▶ The derivative of a function is zero at every local maximum
- ▶ Zero derivative points are not local maxima in general.
- ▶ To be a local maximum, the curvature must be negative

13 / 29

Maximum Likelihood and Optimization

How can we find the model parameters θ that maximize the likelihood?

- ▶ Compute the (partial) derivatives of the log likelihood
- ▶ Set them equal to zero
- ▶ Solve derivative equations for the parameters
- ▶ (Determine which solutions are local maxima by checking second derivatives)

14 / 29

MLE Examples

15 / 29

Example: Bernoulli Parameter Learning

The maximum likelihood estimates for the simple Bernoulli model are easy to derive:

- ▶ $\mathcal{L}(\theta|x^{(1:N)}) = \frac{\#(X=0)}{N} \log(1-\theta) + \frac{\#(X=1)}{N} \log \theta$
- ▶ $\frac{\partial}{\partial \theta} \mathcal{L}(\theta|x^{(1:N)}) = \frac{\#(X=1)}{N\theta} - \frac{\#(X=0)}{N(1-\theta)}$
- ▶ Setting the derivative equation equal to zero and solving yields the maximum likelihood estimate:

$$\theta = \frac{\#(X=1)}{N}$$

16 / 29

Example: Multinomial Model

Consider a Multinomial model for a discrete random variable X that takes V values $\{1, \dots, V\}$.

$$p_{\theta}(x) = \begin{cases} \theta_1 & x = 1 \\ \vdots \\ \theta_{V-1} & x = V-1 \\ 1 - \sum_{v=1}^{V-1} \theta_v & x = V \end{cases}$$

Then

$$\begin{aligned} \mathcal{L}(\theta|x^{(1:N)}) &= \frac{1}{N} \sum_{n=1}^N \left(\sum_{v=1}^{V-1} \mathbb{I}[x^{(n)} = v] \log(\theta_v) + \mathbb{I}[x^{(n)} = V] \log\left(1 - \sum_{v=1}^{V-1} \theta_v\right) \right) \\ &= \sum_{v=1}^{V-1} \frac{\#(X = v)}{N} \log(\theta_v) + \frac{\#(X = V)}{N} \log\left(1 - \sum_{v=1}^{V-1} \theta_v\right) \end{aligned}$$

17 / 29

Example: Multinomial Parameter Learning

$$\mathcal{L}(\theta|x^{(1:N)}) = \sum_{v=1}^{V-1} \frac{\#(X = v)}{N} \log(\theta_v) + \frac{\#(X = V)}{N} \log\left(1 - \sum_{v=1}^{V-1} \theta_v\right)$$

▶ Setting the partial derivatives to zero, we require, for each $i < V$:

$$\frac{\partial}{\partial \theta_i} \mathcal{L}(\theta|x^{(1:N)}) = \frac{\#(X = i)}{N \theta_i} - \frac{\#(X = V)}{N(1 - \sum_{v=1}^{V-1} \theta_v)} = 0$$

▶ It's easy to check that this is solved by setting

$$\theta_i = \frac{\#(X = i)}{N}$$

18 / 29

Learning Bayesian Networks

19 / 29

Bayesian Network Parameters

In a Bayesian network, each CPT is a *collection* of multinomial distributions with distinct parameters. There is one multinomial distribution for each joint setting of the parents of each variable.

HD	G	BP	C	$P(HD G, BP, C)$
No	M	Low	Low	$\theta_{N M,L,L}^{HD}$
Yes	M	Low	Low	$\theta_{Y M,L,L}^{HD}$
No	F	Low	Low	$\theta_{N F,L,L}^{HD}$
Yes	F	Low	Low	$\theta_{Y F,L,L}^{HD}$
⋮	⋮	⋮	⋮	⋮

$$\log P(HD = h|G = g, BP = b, C = c) = \log \theta_{h|g,b,c}^{HD}$$

20 / 29

Joint Probability in Terms of Parameters

The joint probability in a Bayesian network is a product of conditional multinomial distribution for each node:

$$p_{\theta}(\mathbf{x}) = \prod_{d=1}^D p_{\theta}(x_d | \mathbf{x}_{\text{pa}(d)}) = \prod_{d=1}^D \theta_{x_d | \mathbf{x}_{\text{pa}(d)}}^{X_d}$$

⇒ log-likelihood is a sum of terms:

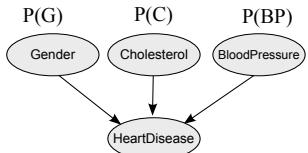

$$\log p_{\theta}(\mathbf{x}) = \sum_{d=1}^D \log \theta_{x_d | \mathbf{x}_{\text{pa}(d)}}^{X_d}$$

Log Likelihood Decomposition

The log likelihood of a dataset $\mathbf{x}^{(1:N)}$ for a Bayesian network decomposes into a sum of terms that depend only on the parameters for one conditional distribution:

$$\begin{aligned} \mathcal{L}(\theta | \mathbf{x}^{(1:N)}) &= \frac{1}{N} \sum_{n=1}^N \sum_{d=1}^D \log \theta_{x_d^{(n)} | \mathbf{x}_{\text{pa}(d)}^{(n)}}^{X_d} \\ &= \frac{1}{N} \sum_{n=1}^N \sum_{d=1}^D \sum_{x_d} \mathbb{I}[x_d^{(n)} = x_d, \mathbf{x}_{\text{pa}(d)}^{(n)} = \mathbf{x}_{\text{pa}(d)}] \log \theta_{x_d | \mathbf{x}_{\text{pa}(d)}}^{X_d} \\ &= \sum_{d=1}^D \sum_{x_d} \sum_{\mathbf{x}_{\text{pa}(d)}} \frac{\#(X_d = x_d, \mathbf{X}_{\text{pa}(d)} = \mathbf{x}_{\text{pa}(d)})}{N} \log \theta_{x_d | \mathbf{x}_{\text{pa}(d)}}^{X_d} \end{aligned}$$

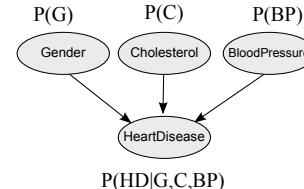

Example: Heart Disease Joint Distribution

$P(\text{HD}|G,C,BP)$

$$p_{\theta}(g, c, b, h) = p_{\theta}(g)p_{\theta}(b)p_{\theta}(c)p_{\theta}(h|g, b, c)$$

Example: Heart Disease Log Likelihood

$$\mathcal{L}(\theta | \mathbf{x}^{(1:N)}) = \sum_g \frac{\#(G = g)}{N} \log \theta_g^G + \sum_b \frac{\#(BP = b)}{N} \log \theta_b^{BP} + \sum_c \frac{\#(C = c)}{N} \log \theta_c^C$$

$$+ \sum_{g,b,c} \sum_h \frac{\#(HD = h, G = g, BP = b, C = c)}{N} \log \theta_{h|g,b,c}^{HD}$$

Bayesian Network Learning Summary

- ▶ The only parameters that must be jointly optimized in a Bayesian network are those in the same sum-to-one constraint with the same setting of the parent variables.
- ▶ For any random variable X , consider a specific setting of its parent variables $\mathbf{Y} = \mathbf{y}$. We just need to jointly optimize the parameters $\theta_{x|\mathbf{y}}^X$ for each value $x \in \text{Val}(X)$.
- ▶ This is just multinomial parameter estimation applied to each variable X for each setting \mathbf{y} of its parents:

$$P_\theta(X = x | \mathbf{Y} = \mathbf{y}) = \theta_{x|\mathbf{y}}^X = \frac{\#(X = x, \mathbf{Y} = \mathbf{y})}{\#(\mathbf{Y} = \mathbf{y})}$$

Page: 28 / 29

Bayesian Network Learning Algorithm

- ▶ For each random variable X_d :
 - ▶ For each joint configuration $\mathbf{x}_{\text{pa}(d)} \in \text{Val}(\mathbf{X}_{\text{pa}(d)})$:
 - ▶ For each value $x_d \in \text{Val}(X_d)$. Set

$$\theta_{x_d|\mathbf{x}_{\text{pa}(d)}}^X \leftarrow \frac{\#(X_d = x_d, \mathbf{X}_{\text{pa}(d)} = \mathbf{x}_{\text{pa}(d)})}{\#(\mathbf{X}_{\text{pa}(d)} = \mathbf{x}_{\text{pa}(d)})}$$
